Follow up regularly with patients to determine whether opioids are meeting treatment goals and whether opioids can be reduced to lower dosage or discontinued.

*Recommendations focus on pain lasting longer than 3 months or past the time of normal tissue healing, outside of active cancer treatment, palliative care, and end-of-life care.
Consider tapering to a reduced opioid dosage or tapering and discontinuing opioid therapy when your patient:

- requests dosage reduction
- does not have clinically meaningful improvement in pain and function (e.g., at least 30% improvement on the 3-item PEG scale)
- is on dosages ≥ 50 MME*/day without benefit or opioids are combined with benzodiazepines
- shows signs of substance use disorder (e.g. work or family problems related to opioid use, difficulty controlling use)
- experiences overdose or other serious adverse event
- shows early warning signs for overdose risk such as confusion, sedation, or slurred speech

*morphine milligram equivalents
HOW TO TAPER

Tapering plans should be individualized and should minimize symptoms of opioid withdrawal while maximizing pain treatment with nonpharmacologic therapies and nonopioid medications. In general:

A decrease of 10% of the original dose per week is a reasonable starting point. Some patients who have taken opioids for a long time might find even slower tapers (e.g., 10% per month) easier.

*Discuss the increased risk for overdose if patients quickly return to a previously prescribed higher dose.*

Coordinate with specialists and treatment experts as needed—especially for patients at high risk of harm such as pregnant women or patients with an opioid use disorder.

*Use extra caution during pregnancy due to possible risk to the pregnant patient and to the fetus if the patient goes into withdrawal.*

Make sure patients receive appropriate psychosocial support. If needed, work with mental health providers, arrange for treatment of opioid use disorder, and offer naloxone for overdose prevention.

*Watch for signs of anxiety, depression, and opioid use disorder during the taper and offer support or referral as needed.*

Let patients know that most people have improved function without worse pain after tapering opioids. Some patients even have improved pain after a taper, even though pain might briefly get worse at first.

*Tell patients “I know you can do this” or “I’ll stick by you through this.”*
1 Adjust the rate and duration of the taper according to the patient’s response.

2 Don’t reverse the taper; however, the rate may be slowed or paused while monitoring and managing withdrawal symptoms.

3 Once the smallest available dose is reached, the interval between doses can be extended and opioids may be stopped when taken less than once a day.
